11–3 Exploring Mendelian Genetics 🛸 Independent Assortment

Independent Assortment

To determine if the segregation of one pair of alleles affects the segregation of another pair of alleles, Mendel performed a two-factor cross. The Two-Factor Cross: F_1

Mendel crossed true-breeding plants that produced round yellow peas (genotype *RRYY*) with true-breeding plants that produced wrinkled green peas (genotype *rryy*).

All of the F_1 offspring produced round yellow peas (*RrYy*).

The alleles for round (R) and yellow (Y) are dominant over the alleles for wrinkled (r) and green (y).

Slide 3 of 31 11–3 Exploring Mendelian Genetics 🛸 Independent Assortment

The Two-Factor Cross: F₂

Mendel crossed the heterozygous F_1 plants (*RrYy*) with each other to determine if the alleles would segregate from each other in the F_2 generation.

 $RrYy \times RrYy$

The Punnett square predicts a

9:3:3:1 ratio in the F₂

generation.

11–3 Exploring Mendelian Genetics Independent Assortment

In Mendel's experiment, the F_2 generation produced the following:

- some seeds that were round and yellow
- some seeds that were wrinkled and green
- some seeds that were round and green
- some seeds that were wrinkled and yellow

Slide 5 of 31 The alleles for seed shape segregated independently of those for seed color. This principle is known as **independent assortment**.

Genes that segregate independently do not influence each other's inheritance.

Mendel's experimental results were very close to the 9:3:3:1 ratio predicted by the Punnett square.

Mendel had discovered the principle of independent assortment.

Slide 6 of 31

11–3 Exploring Mendelian Genetics 🛸 Independent Assortment

The principle of independent assortment states that genes for different traits can segregate independently during the formation of gametes.

Independent assortment helps account for the many genetic variations observed in plants, animals, and other organisms.

11–3 Exploring Mendelian Genetics A Summary of Mendel's Principles

A Summary of Mendel's Principles

- Genes are passed from parents to their offspring.
- If two or more forms (alleles) of the gene for a single trait exist, some forms of the gene may be dominant and others may be recessive.
- In most sexually reproducing organisms, each adult has two copies of each gene. These genes are segregated from each other when gametes are formed.
- The alleles for different genes usually segregate independently of one another.

Slide 11 of 31

- In a cross involving two pea plant traits, observation of a 9 : 3 : 3 : 1 ratio in the F₂ generation is evidence for
 - a. the two traits being inherited together.
 - b. an outcome that depends on the sex of the parent plants.
 - c. the two traits being inherited independently of each other.
 - d. multiple genes being responsible for each trait.

Slide 12 of 31

5

Mendel's principles apply to

- a. pea plants only.
- b. fruit flies only.
- c. all organisms.
- d. only plants and animals.
